# Lab 8

## Meihe Liu

## 11:59PM April 29, 2021

I want to make some use of my CART package. Everyone please try to run the following:

```
if (!pacman::p_isinstalled(YARF)){
  pacman::p_install_gh("kapelner/YARF/YARFJARs", ref = "dev")
  pacman::p_install_gh("kapelner/YARF/YARF", ref = "dev", force = TRUE)
}
options(java.parameters = "-Xmx4000m")
pacman::p_load(YARF)
```

For many of you it will not work. That's okay.

Throughout this part of this assignment you can use either the tidyverse package suite or data.table to answer but not base R. You can mix data.table with magrittr piping if you wish but don't go back and forth between tbl\_df's and data.table objects.

```
pacman::p_load(tidyverse, magrittr, data.table)
```

We will be using the **storms** dataset from the **dplyr** package. Filter this dataset on all storms that have no missing measurements for the two diameter variables, "ts diameter" and "hu diameter".

```
data(storms)
storms2 = storms %>%
  filter(!is.na(ts_diameter) & !is.na(hu_diameter) & hu_diameter>0)
storms2
```

```

Using this long-formatted data frame, use a line plot to illustrate both "ts\_diameter" and "hu\_diameter" metrics by observation period for four random storms using a 2x2 faceting. The two diameters should appear in two different colors and there should be an appropriate legend.

In this next first part of this lab, we will be joining three datasets in an effort to make a design matrix that predicts if a bill will be paid on time. Clean up and load up the three files. Then I'll rename a few features and then we can examine the data frames:

```
rm(list = ls())
pacman::p_load(tidyverse, magrittr, data.table, R.utils)
bills = fread("https://github.com/kapelner/QC_MATH_342W_Spring_2021/raw/master/labs/bills_dataset/bills
payments = fread("https://github.com/kapelner/QC_MATH_342W_Spring_2021/raw/master/labs/bills_dataset/pa
discounts = fread("https://github.com/kapelner/QC_MATH_342W_Spring_2021/raw/master/labs/bills_dataset/d
setnames(bills, "amount", "tot_amount")
setnames(payments, "amount", "paid_amount")
head(bills)
##

bills = as_tibble(bills)
payments = as tibble(payments)
discounts = as_tibble(discounts)
The unit we care about is the bill. The y metric we care about will be "paid in full" which is 1 if the company
paid their total amount (we will generate this y metric later).
Since this is the response, we would like to construct the very best design matrix in order to predict y.
I will create the basic steps for you guys. First, join the three datasets in an intelligent way. You will need to
examine the datasets beforehand.
bills_with_payments = left_join(bills, payments, by =c("id"= "bill_id"))
bills_with_payments

## # transaction_date <date>, num_days <int>, pct_off <dbl>,
## # days_until_discount <int>
```

Now create the binary response metric paid\_in\_full as the last column and create the beginnings of a design matrix bills\_data. Ensure the unit / observation is bill i.e. each row should be one bill!

```
bills_data = bills_with_payments_with_discounts%>%
   mutate(tot_amount = if_else(is.na(pct_off),tot_amount,tot_amount*(1-pct_off/100 )))%>%
   group_by(id)%>%
   mutate(sum_of_payment_amount = sum(paid_amount))%>%
   mutate(paid_in_full = if_else(sum_of_payment_amount >=tot_amount,1,0,missing = 0))%>%
   slice(1)%>%
   ungroup()
table(bills_data$paid_in_full, useNA = "always")
```

```
## ## 0 1 <NA>
## 112664 113770 0
```

How should you add features from transformations (called "featurization")? What data type(s) should they be? Make some features below if you think of any useful ones. Name the columns appropriately so another data scientist can easily understand what information is in your variables.

```
pacman::p_load("lubridate")
bills_data = bills_data %>%
    select(-id, -id.y, -num_days, -transaction_date, -pct_off, -days_until_discount, -sum_of_payment_amous
    mutate(num_days_to_pay = as.integer(ymd(due_date) - ymd(invoice_date))) %>%
    select(-due_date, -invoice_date) %>%
    mutate(discount_id = as.factor(discount_id)) %>%
    group_by(customer_id) %>%
    mutate(bill_num = row_number()) %>%
    ungroup() %>%
    select(-customer_id) %>%
    relocate(paid in full, .after = last col())
```

Now let's do this exercise. Let's retain 25% of our data for test.

```
K = 4
test_indices = sample(1 : nrow(bills_data), round(nrow(bills_data) / K))
train_indices = setdiff(1 : nrow(bills_data), test_indices)
bills_data_test = bills_data[test_indices, ]
bills_data_train = bills_data[train_indices, ]
```

Now try to build a classification tree model for paid\_in\_full with the features (use the Xy parameter in YARF). If you cannot get YARF to install, use the package rpart (the standard R tree package) instead. You will need to install it and read through some documentation to find the correct syntax.

Warning: this data is highly anonymized and there is likely zero signal! So don't expect to get predictive accuracy. The value of the exercise is in the practice. I think this exercise (with the joining exercise above) may be one of the most useful exercises in the entire semester.

```
install.packages('rpart')
## Installing package into '/home/rstudio-user/R/x86_64-pc-linux-gnu-library/4.0'
## (as 'lib' is unspecified)
```

```
pacman::p_load(rpart)
mod1 = rpart(paid_in_full ~., data = bills_data_train, method = "class")
mod1

For those of you who installed YARF, what are the number of nodes and depth of the tree?

### nrow(mod1\$frame)

### ## [1] 11

For those of you who installed YARF, print out an image of the tree.

```
plot(mod1, uniform=TRUE)
text(mod1, use.n=TRUE, all=TRUE, cex=.5)
```

Predict on the test set and compute a confusion matrix.

```
yhat = predict(mod1, bills_data_test, type = c("class"), na.action = na.pass)
oos_confus_matrix = table(bills_data_test$paid_in_full,yhat )
oos_confus_matrix
```

```
## yhat
## 0 1
15991 12175
```

#### ## 1 3573 24869

n = sum(oos\_confus\_matrix)
fp = oos\_confus\_matrix[1, 2]
fn = oos\_confus\_matrix[2, 1]

 $0.001, 0.002, \ldots, 0.999$  in a data frame.

#we first make the grid of all prob thresholds

Report the following error metrics: misclassification error, precision, recall, F1, FDR, FOR.

```
tp = oos_confus_matrix[2, 2]
tn = oos_confus_matrix[1, 1]
num_predicted_pos = sum(oos_confus_matrix[, 2])
num_predicted_neg = sum(oos_confus_matrix[, 1])
num_pos = sum(oos_confus_matrix[2, ])
num_neg = sum(oos_confus_matrix[1, ])
precision = tp / num_predicted_pos
cat("precision", round(precision * 100, 2), "%\n")
## precision 67.13 %
recall = tp / num pos
cat("recall", round(recall * 100, 2), "%\n")
## recall 87.44 %
FDR = 1 - precision
cat("FDR", round(FDR * 100, 2), "%\n")
## FDR 32.87 %
FOR = fn / num_predicted_neg
cat("FOR", round(FOR * 100, 2), "%\n")
## FOR 18.26 %
ME = (fn + fp)/n
cat("ME", round(ME * 100, 2), "\n")
## ME 27.82 %
Is this a good model? (yes/no and explain).
#TO-DO
There are probability asymmetric costs to the two types of errors. Assign the costs below and calculate oos
total cost.
cost_fp = 100
cost_fn = 1
oos_total_cost = (cost_fn * fn) + (cost_fp * fp)
oos_total_cost
## [1] 1221073
We now wish to do asymmetric cost classification. Fit a logistic regression model to this data.
logistic_regression_mod = glm(paid_in_full ~., bills_data_train, family = binomial(link = "logit"))
```

Use the function from class to calculate all the error metrics for the values of the probability threshold being

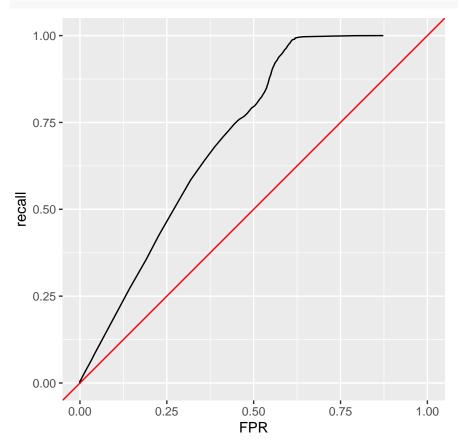

compute\_metrics\_prob\_classifier = function(p\_hats, y\_true, res = 0.001){

p\_thresholds = seq(0 + res, 1 - res, by = res) #values of 0 or 1 are trivial

```
#now we create a matrix which will house all of our results
performance_metrics = matrix(NA, nrow = length(p_thresholds), ncol = 12)
colnames(performance_metrics) = c(
  "p th",
  "TN",
  "FP",
  "FN",
  "TP",
  "miscl_err",
  "precision",
  "recall",
  "FDR",
  "FPR",
  "FOR",
  "miss_rate"
#now we iterate through each p_th and calculate all metrics about the classifier and save
n = length(y_true)
for (i in 1 : length(p_thresholds)){
  p th = p thresholds[i]
  y_hats = factor(ifelse(p_hats >= p_th, 1, 0))
